**Investigating resting-state functional connectivity of
the ventral anterior intraparietal area:
an offline TMS-fMRI study**

Pierotti, E., Speranza, C., Cattaneo, L. & Turella, L.

University of Trento

XXXI Congresso Nazionale SIPF

Siena, 10/11/2023

Background

- ✓ Parietal complex: crucial hub for upper limb control in monkeys
- ✓ Hub of the Dorsolateral pathway involved in visuo-motor transformations for grasping/object manipulation
- ✓ Widespread connectivity with the:
 - ✓ Dorsolateral pathway
 - ✓ Dorsomedial pathway
 - ✓ Ventral pathway

Background

Research question:

Is the connectivity of the human vaIPS similar to the connectivity of the monkey parietal complex?

Aim:

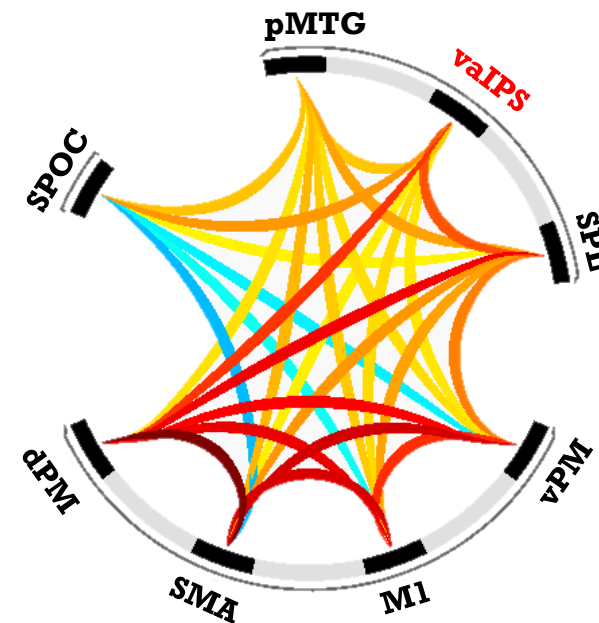

Is the connectivity of the human vaIPS similar to the connectivity of the monkey parietal complex?

How?

Testing the modifications in resting-state functional connectivity after TMS stimulation

Resting State Functional connectivity (FC)

Positive
FC

Negative
FC

Methods

32 participants
(6 excluded)
Right-handed

MRI-guided neuronavigation
Continuous theta-burst stimulation (cTBS)

Huang et al., 2005

Analysis

1. ROI-to-ROI connectivity analysis

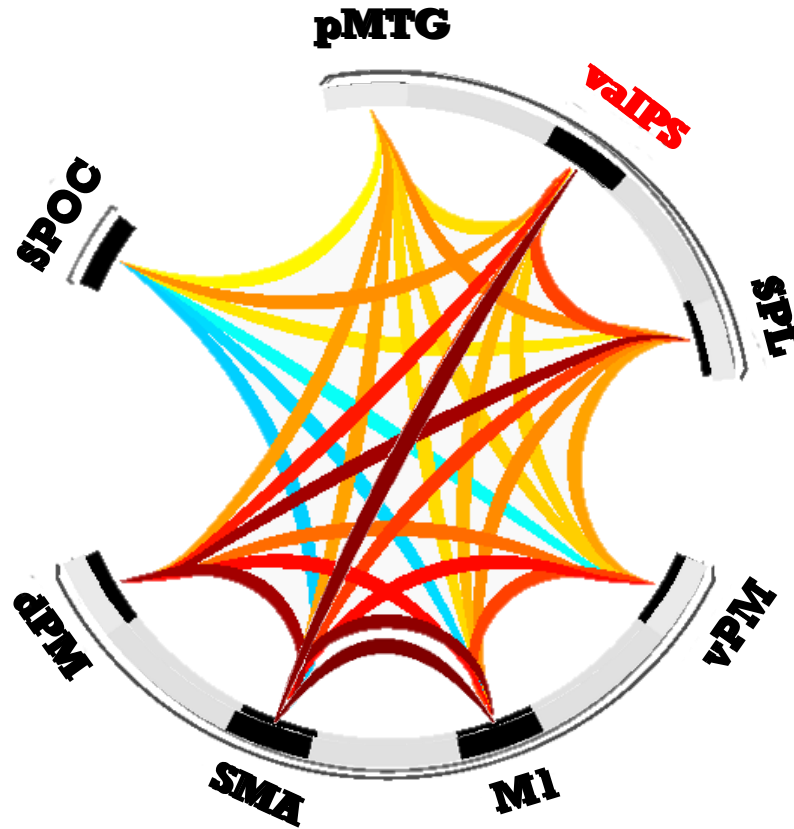

Results

PRE-TMS

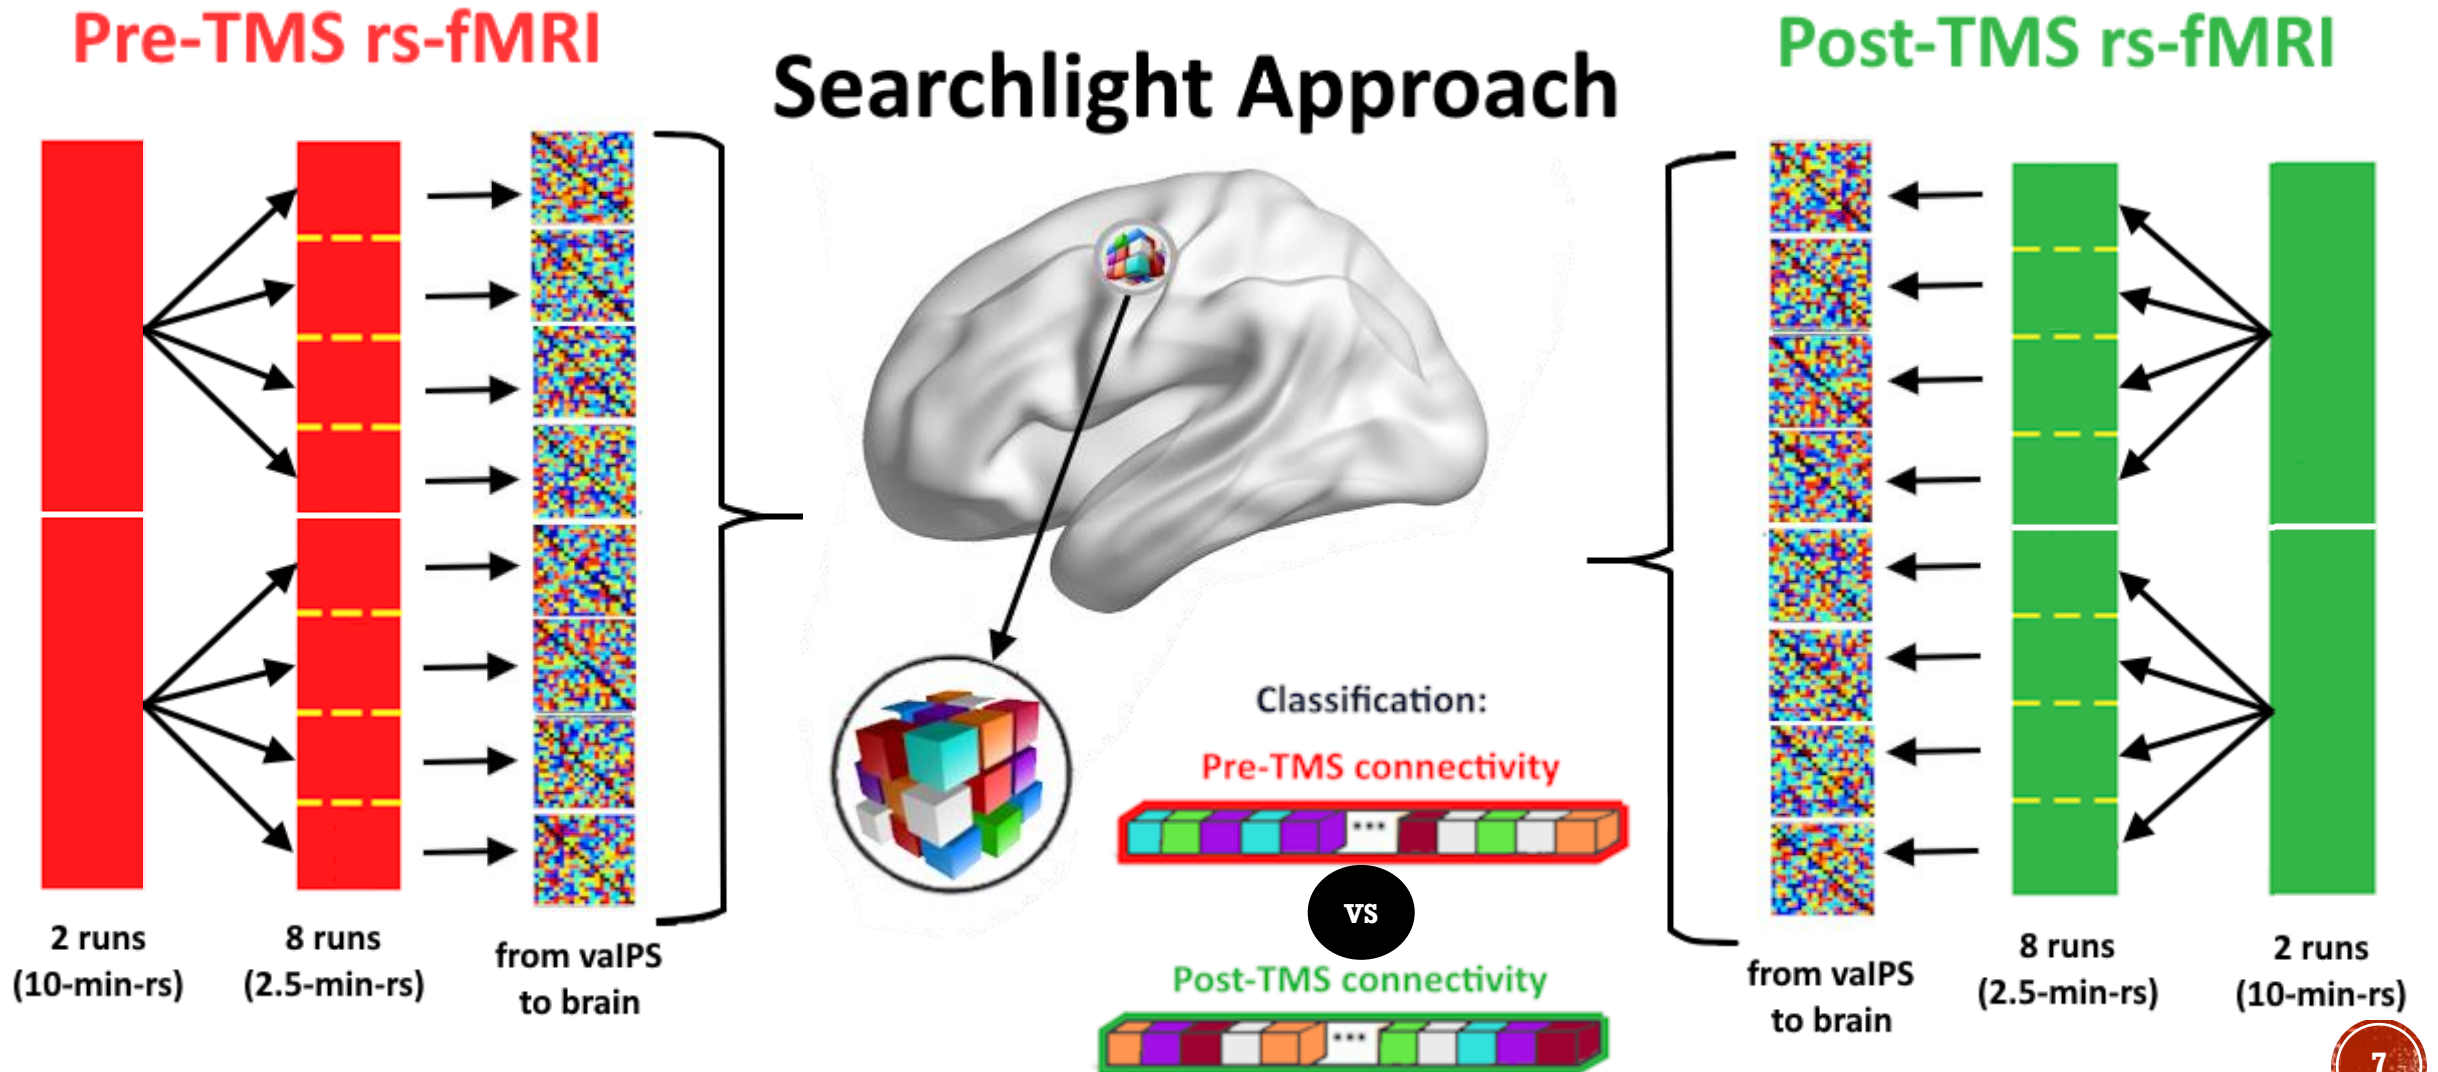

POST-TMS

q < 0.05 (FDR-corrected, two-tailed)

2. Multivariate approach based on vaIPS Seed-Based Connectivity

2. Searchlight results

L

R

Prefrontal cortex

9.85

t-values

3.45

Cluster $p < 0.05$
FDR corrected

Conclusions

Research question:

Is the connectivity of the human vaIPS similar to the connectivity of the monkey parietal complex?

1. ROI-to-ROI univariate analysis showed an unexpected pattern of connectivity:

TMS over vaIPS increased the connectivity between vaIPS and SMA and between SMA and M1

2. Multivariate analysis showed a pattern of connectivity in line with monkey:

Widespread change in connectivity in the dorsolateral, dorsomedial and ventral pathways together with modifications in the prefrontal cortex
